

PEPTIDES FOR INDUCING CYTOTOXIC T  
LYMPHOCYTE RESPONSES TO HEPATITIS C VIRUS.

GOVERNMENT SUPPORT

The U.S. Government may have certain rights in this invention pursuant to grants awarded by the National Institutes of Health.

5

TECHNICAL FIELD OF THE INVENTION

The present invention relates to the isolation and use of compounds having substantial homology to hepatitis C virus-specific cytotoxic T cell lymphocyte epitopes for the immunization and treatment of mammals afflicted with or at risk of exposure to chronic and acute hepatitis C viral hepatitis.

10

BACKGROUND OF THE INVENTION

Hepatitis C virus ("HCV") was originally identified as a causative agent of transfusion-associated hepatitis that had a propensity to induce acute and chronic hepatitis and hepatocellular carcinoma. Choo et al., Science, 244, 359-362 (1989). It is a major cause of morbidity and mortality worldwide, considering that at least 50% of infected persons will develop chronic hepatitis, and 20% of these will further develop cirrhosis. Dienstag, Gastroenterology, 85, 439 (1983). No cure is currently available for treatment of chronic or acute HCV infection.

25

The complete nucleotide sequence and genetic organization of HCV has been fully elucidated by Choo et al., Proc. Natl. Acad. Sci. USA, 88, 2451-2455 (1991). The HCV genome of positive-stranded RNA consists of 9,379 nucleotides and has a single large open reading frame that could encode a viral polyprotein precursor of 3,011 amino acids. Although there is little overall similarity in sequence between that of HCV and other viruses whose sequence is known, a portion of the sequence (upstream of

30

033425 "051297

Ans.  
C1

the 5' end of the open reading frame) is similar to the analogously positioned sequence of pestiviral genomes. The polyprotein also displays significant sequence similarity to helicases encoded by animal pestiviruses and human flaviviruses, among others. Comparison of the hydrophobicity profiles of the sequence of encoded amino acids, and comparison of such a profile between HCV and a flavivirus (yellow fever virus), for example, has resulted in the assignment of regions of the HCV genome as relating to proteins forming the capsid or core (C), and the envelope (E1 and E2), as well as five regions that specify nonstructural proteins (NS1 through NS5).

The mechanisms whereby HCV causes acute hepatocellular injury and initiates the sequence of events leading to chronic liver disease and ultimately to hepatocellular carcinoma are not well understood. It is possible that both virus-related direct and immunologically-mediated indirect mechanisms play important roles in HCV chronic hepatitis. For example, a link between HCV infection and the presence of autoantibodies is well-established. Lenzi et al., Lancet, 338, 277-280 (1991). Unfortunately, analysis of the direct cytopathic effect of HCV for host liver cells has been hampered due to the lack of suitable animal models and tissue culture systems.

Several clinical observations support the hypothesis that the host immune response contributes to liver cell injury: first, infection acquired early in life occurring in an immunologically immature host leads to a chronic asymptomatic carrier state; second, chronic carriers without evidence of liver cell injury are common; and third, immunosuppression has a beneficial effect on liver cell injury in chronic hepatitis C. See Alter, in Viral Hepatitis And Liver Disease, (Hollinger et al., eds., 1991), 410-413. A recent report also demonstrated the presence of an HCV-specific, major histocompatibility

08654825 091597

5 specifically, it is generally presumed that the

response to viral antigens is almost entirely T-cell dependent. Even the antibody response requires T-cell help. Thus susceptibility to virus infections is particularly associated with T cell dysfunction, though this tells us little about the effector mechanisms involved, since T cells are required both for antibody production and for some cytotoxic reactions.

Accordingly, central to the host immune response to attack by an intracellular agent (e.g., an infecting virus, bacterium, or other intracellular parasite) would be that which is mediated by the cellular immune system; in particular, by HLA class I CTL's. Class I antigens are cell surface glycoproteins that control the recognition by CTL's of modified (i.e., infected or otherwise altered, as in cancer) self cells, and of foreign cells. CTL-mediated lysis of virus infected host cells may lead to clearance of the virus or, if incomplete, such lysis may lead to viral persistence and eventually chronic tissue injury. Viral persistence and immunologically-mediated liver injury are thought to be important mechanisms leading to chronic hepatitis C after infection with HCV.

At its most fundamental level, the cellular immune response involves a multimolecular interaction between antigenic peptides, HLA molecules and T cell receptors ("TCR") on the CTL. Unlike antigen recognition by B cell immunoglobulin receptors, the two general classes of T cells do not recognize native antigen in solution; rather, they recognize short antigenic peptides that have reached the cell surface via two quite different pathways

(reviewed in Rothbard et al., Ann. Rev. Immunol., 9, 527-565 (1991); also, see Rötzschke et al., Immunol. Today, 12, 447-455 (1991)). The subject matter of the present invention centers on the induction of activity by one of these pathways, namely that involving the human CD8<sup>+</sup> T cell and its counterpart in other mammalian species.

Human CD8<sup>+</sup> T cells recognize short antigenic peptides (usually 9-11 residues in length) once presented to the antigen binding groove of HLA class I molecules.

The antigen binding grooves, and, more generally, HLA class I molecules, are present at the surface of the cells in which each HLA class I molecule's precursor proteins were originally synthesized. As reported by Monaco (Immunol. Today, 13, 173-179 (1992)), such precursor proteins may be derived from an infecting virus. Accordingly, the antigenic peptides, processed within the CTL, are derived by proteolytic cleavage of endogenously synthesized antigen in the cytoplasm. The processed peptides are then bound by a family of transporter proteins (encoded within the HLA locus) that shuttle them into the lumen of the endoplasmic reticulum where they are scanned for the presence of HLA allele specific binding motifs by the antigen binding domain of resident HLA class I proteins. Peptides containing the appropriate motif are bound by the corresponding HLA class I molecule, which then associates with  $\beta_2$ -microglobulin and moves to the cell surface as an integral membrane protein. At the cell surface, the integral membrane protein can present the antigenic peptide to the appropriately rearranged TCR on a CD8<sup>+</sup> T cell. The T cell subset specificity of this interaction derives from the fact that the multimolecular HLA-peptide-TCR complex is stabilized by accessory interactions such as those between the CD8 molecule on the T cell and the HLA class I molecule involved in the complex.

At the present time, it is difficult to predict from the sequence of an antigenic protein how the protein will be processed and which peptide portions will bind HLA class I molecules and be presented to CTL's. Binding motifs have been predicted for some HLA class I molecules based on sequence analysis of peptides eluted from these molecules. Falk et al., Nature, 351, 290 (1991). However, not all peptides that match the motif will be recognized as CTL-recognizable epitopes. Moreover, even of the peptides that are processed and bind to HLA class I molecules, identifying which ones will contain CTL-recognizable epitopes is not yet predictable.

Due to work in other systems, it has been assumed that the HLA class I restricted, CD8<sup>+</sup> CTL response to endogenously synthesized HCV antigens is responsible for the observed pathological consequences of chronic infection by this virus. Mondelli et al., Arch. Pathol. Lab. Med., 112, 489 (1988). This hypothesis was untestable until recently due to the absence of the necessary reagents and experimental systems. HCV has not been demonstrated to infect continuous human cell lines in tissue culture, and the only animal model of HCV (chimpanzee) infection that could be used for such studies involves a species for which the immune system is not sufficiently defined.

Irrespective of the mode of activity, it is evident that the CTL response with respect to HCV is deficient in cases of chronic HCV disease. Moreover, there are a large number of individuals who, having been infected with HCV, have since developed chronic HCV hepatitis. It would be desirable to stimulate the immune response in these individuals to respond to appropriate HCV antigens and thereby eliminate their infection. It would also be desirable to prevent the progression of an acute phase HCV infection to a chronic phase infection. Further, as there is no currently available vaccine for HCV infection

## BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a bar graph that displays HCV-specific CTL responses observed after initial in vitro expansion of the CTL's in the presence of HCV-derived peptides.

5 The abscissa sets forth each of seven HCV peptides (detailed in Example 3) and the ordinate sets forth the percentage specific cytotoxicity.

Figure 2 is a set of three graphs that display cytotoxic activity of CTL lines specific for three HCV peptides (detailed in Example 3). The abscissa sets forth the effector/target cell ratio and the ordinate sets forth the percentage specific lysis.

Figure 3 is a set of four graphs that displays the results of a HLA class I restriction analysis (detailed in Example 3). The abscissa sets forth the effector/target cell ratio and the ordinate sets forth the percentage specific lysis.

Figure 4 is a set of two graphs that demonstrates the results of an assay regarding the recognition and lysis of target cells that have been caused to synthesize specific viral antigen endogenously (detailed in Example 3). The abscissa sets forth the effector/target cell ratio and the ordinate sets forth the percentage specific lysis.

25

## DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention provides certain polypeptides that stimulate HLA class I restricted cytotoxic T lymphocyte ("CTL") responses against certain HCV antigens, particularly when such antigens are expressed in a host cell that has been infected by HCV. Such polypeptides are useful in compositions and methods for the treatment, prevention, and diagnosis of HCV infection, whether in its acute or chronic phase. The stimulated CTL's kill HCV-infected cells, thereby preventing, impeding, or reversing the course of HCV

0854325.031297

infection. Novel combinations of epitopes are contemplated within the context of the present invention, such that the CTL response described in brief above, and in greater detail below, is combined with a T-helper response or multiple CTL response directed at different HCV antigens, for example.

The polypeptides of interest are derived from various regions of the HCV genome, including the core (e.g., ADLMGYIPLV (Core<sub>131-140</sub>; SEQ ID NO:1) and LLALLSCLTV (Core<sub>178-187</sub>; SEQ ID NO:2)), NS3 (e.g., LLCPAGHAV (NS3<sub>1169-1177</sub>; SEQ ID NO:26) and KLVALGINAV (NS3<sub>1406-1415</sub>; SEQ ID NO:28)), NS4 (e.g., SLMAFTAAV (NS4<sub>1789-1797</sub>; SEQ ID NO:34) and LLFNILGGWV (NS4<sub>1807-1816</sub>; SEQ ID NO:35)), NS5 (e.g., ILDSFDPLV (NS5<sub>2252-2260</sub>; SEQ ID NO:42)). Numeric positions on the HCV genome are in accordance with Choo et al., Proc. Natl. Acad. Sci. USA, 88, 2451-2455 (1991).

In certain embodiments of the present invention, the polypeptides of interest will have the sequences just recited as well as others listed below, or will have sequences that are substantially homologous thereto. Two polypeptides are said to be substantially homologous if at least 50% of the amino acid ("aa") residues are the same in the same or analogous position. By analogous position, it is intended the relative position of the polypeptide of interest itself, regardless of any flanking polypeptide or other chemical elements that may be attached to the polypeptide of interest.

Preferred peptides employed in the subject invention, accordingly, need not be identical, but are at least substantially homologous, to the following peptides: ADLMGYIPLV (Core<sub>131-140</sub>; SEQ ID NO:1), DLMGYIPLV (Core<sub>132-140</sub>; SEQ ID NO:54), LLALLSCLTV (Core<sub>178-187</sub>; SEQ ID NO:2), LLCPAGHAV (NS3<sub>1169-1177</sub>; SEQ ID NO:26), KLVALGINAV (NS3<sub>1406-1415</sub>; SEQ ID NO:28), SLMAFTAAV (NS4<sub>1789-1797</sub>; SEQ ID NO:34), LLFNILGGWV (NS4<sub>1807-1816</sub>; SEQ ID NO:35), ILDSFDPLV (NS5<sub>2252-2260</sub>; SEQ ID NO:42), and QLRRHIDLLV (SEQ ID NO:55).

EL 252-464, SEQ ID NO:3

005433 "05123"

B

The subject compounds have the ability to stimulate cytotoxic T lymphocytic activity against at least one major subtype of HCV. Such subtypes of HCV have been described by Houghten et al., Hepatology, 14, 381-388 (1991).

The present invention relates to a polypeptide having substantial homology with a CTL epitope selected from the same group of polypeptides identified above. Preferred polypeptides include LLCPAGHAV (NS3<sub>1169-1177</sub>; SEQ ID NO:26), KLVALGINAV (NS3<sub>1406-1415</sub>; SEQ ID NO:28), SLMAFTAAV (NS4<sub>1789-1797</sub>; SEQ ID NO:34), LLFNILGGWV (NS4<sub>1807-1816</sub>; SEQ ID NO:35), ILDSFDPLV (NS5<sub>2252-2260</sub>; SEQ ID NO:42), and those substantially homologous thereto. More preferred polypeptides include LLCPAGHAV (NS3<sub>1169-1177</sub>; SEQ ID NO:26), KLVALGINAV (NS3<sub>1406-1415</sub>; SEQ ID NO:28), and those substantially homologous thereto. The most preferred polypeptides are KLVALGINAV (NS3<sub>1406-1415</sub>; SEQ ID NO:28), and those substantially homologous thereto.

In particular, the present invention relates to a suitable molecule comprising a polypeptide having substantial homology with one of the CTL epitopes recited above. The molecule of the present invention comprises at least five amino acids and as many as 50 amino acids. A preferred range of amino acids for the molecule of the present invention is from about eight amino acids to less than about twenty-five amino acids. A more preferred range of amino acids is from about nine amino acids to less than about fifteen. A most preferred range of amino acids is from about nine amino acids to less than about 13 amino acids.

It may be desirable to optimize peptides of the invention to a length of eight to twelve amino acid residues, commensurate in size with endogenously processed viral peptides that are bound to major histocompatibility complex ("MHC") class I molecules on the cell surface. See generally, Schumacher et al.,

08354825-09-1097

25  
B

8 to less than about 50 amino acids

Nature, 350, 703-706 (1991); Van Bleek et al., Nature, 348, 213-216 (1990); Rotzschke et al., Nature, 348, 252-254 (1990); and Falk et al., Nature, 351, 290-296 (1991). As set forth in more detail below, usually the peptides will have at least a majority of amino acids that are homologous to a corresponding portion of contiguous residues of the HCV sequences disclosed hereinabove, and contain a CTL-inducing epitope.

The peptides of the present invention can be prepared by any suitable means, such as synthetically using standard peptide synthesis chemistry (described hereinbelow) or by using recombinant DNA technology (also described below). Although the peptide preferably will be substantially free of other naturally occurring HCV proteins and fragments thereof, in some embodiments the peptides can be synthetically conjugated to native fragments or particles, or other compounds that are nonproteinaceous. The term peptide is used interchangeably with polypeptide or oligopeptide in the present specification to designate a series of amino acids connected one to the other by peptide bonds between the alpha-amino and alpha-carboxy groups of adjacent amino acids. The polypeptides or peptides can be any suitable length, either in their neutral (actually zwitterionic) forms or in forms that are salts, and either free of modifications, such as glycosylation, side chain oxidation, or phosphorylation, or containing these modifications, subject to the condition that the modification not destroy the biological activity of the polypeptides, as herein described.

Desirably, the peptide will be as small as possible while still maintaining substantially all of the biological activity of the larger peptides first disclosed herein. By biological activity is meant the ability to bind an appropriate MHC molecule and induce a cytotoxic T lymphocyte response against HCV antigen or

5

10

20

25

35

5  
10

20

25

30

35

attributes, e.g., improved pharmacological characteristics, while increasing or at least retaining substantially the biological activity of the unmodified peptide. For instance, the peptides can be modified by  
5 extending, decreasing or substituting amino acids in the peptide sequence by, for example, the addition or deletion of suitable amino acids on either the amino terminal or carboxy terminal end, or both, of peptides derived from the sequences disclosed herein.

10 The peptides may be modified to enhance substantially the CTL inducing activity, such that the modified peptide analogs have CTL activity greater than a peptide of the wild-type sequence. For example, it may be desirable to increase the hydrophobicity of the N-  
15 terminal of a peptide, particularly where the second residue of the N-terminal is hydrophobic and is implicated in binding to the HLA restriction molecule. By increasing hydrophobicity at the N-terminal, the efficiency of the presentation to T cells may be  
20 increased. Peptides prepared from other disease associated antigens, particularly those containing CTL inducing epitopes for which a host may not have significant CTL activity, may be made CTL-inducing by substituting hydrophobic residues at the N-terminus of  
25 the peptide where the second residue is normally hydrophobic.

Therefore, the peptides may be subject to various changes, such as insertions, deletions, and substitutions, either conservative or non-conservative,  
30 where such changes provide for certain advantages in their use. By conservative substitutions is meant replacing an amino acid residue with another that is biologically and/or chemically similar, e.g., one hydrophobic residue for another, or one polar residue for  
35 another. The substitutions include combinations such as Gly, Ala; Val, Ile, Leu; Asp, Glu; Asn, Gln; Ser, Thr;

Lys, Arg; and Phe, Tyr. Preferably, the portion of the sequence that is intended to mimic substantially a HCV cytotoxic T lymphocyte stimulating epitope will not differ by more than about 20% from the sequence of at least one subtype of HCV, except where additional amino acids may be added at either terminus for the purpose of modifying the physical or chemical properties of the peptide for, for example, ease of linking or coupling, and the like. Where regions of the peptide sequences are found to be polymorphic among HCV subtypes, it may be desirable to vary one or more particular amino acids to mimic more effectively differing cytotoxic T-lymphocyte epitopes of different HCV strains or subtypes.

Within the peptide sequences identified by the present invention, including the representative peptides listed above, there are residues (or those that are substantially functionally equivalent) that allow a particular peptide to retain its biological activity, i.e., the ability to stimulate a class I-restricted cytotoxic T-lymphocytic response against HCV-infected cells or cells that express HCV antigen. These residues can be identified by suitable single amino acid substitutions, deletions, or insertions, followed by suitable assays, such as testing for cytotoxic activity by so-stimulated CTL's.

In addition, the contributions made by the side chains of the residues can be probed via a systematic replacement of individual residues with a suitable amino acid, such as Gly or Ala. Systematic methods for determining which residues of a linear amino acid sequence are required for binding to a specific MHC protein, one of the characteristics of the peptides of the present invention, are known. See, for instance, Allen et al., Nature, 327, 713-717; Sette et al., Nature, 328, 395-399; Takahashi et al., J. Exp. Med.,

170, 2023-2035 (1989); and Maryanski et al., Cell, 60, 63-72 (1990).

Peptides that tolerate multiple amino acid substitutions generally incorporate small, relatively neutral molecules, e.g., Ala, Gly, Pro, or similar residues. The number and types of residues that can be substituted, added or subtracted will depend on the spacing necessary between the essential epitopic points and certain conformational and functional attributes that are sought. By types of residues, it is intended, e.g., to distinguish between hydrophobic and hydrophilic residues, among other attributes. If desired, increased binding affinity of peptide analogs to its MHC molecule for presentation to a cytotoxic T-lymphocyte can also be achieved by such alterations. Generally, any spacer substitutions, additions or deletions between epitopic and/or conformationally important residues will employ amino acids or moieties chosen to avoid steric and charge interference that might disrupt binding.

Peptides that tolerate multiple substitutions while retaining the desired biological activity may also be synthesized as D-amino acid-containing peptides. Such peptides may be synthesized as "inverso" or "retro-inverso" forms, that is, by replacing L-amino acids of a sequence with D-amino acids, or by reversing the sequence of the amino acids and replacing the L-amino acids with D-amino acids. As the D-peptides are substantially more resistant to peptidases, and therefore are more stable in serum and tissues compared to their L-peptide counterparts, the stability of D-peptides under physiological conditions may more than compensate for a difference in affinity compared to the corresponding L-peptide. Further, L-amino acid-containing peptides with or without substitutions can be capped with a D-amino acid to inhibit exopeptidase destruction of the antigenic peptide.

In addition to the exemplary peptides described herein, the present invention provides methods for identifying other epitopic regions associated with said peptide regions capable of inducing MHC-restricted cytotoxic T lymphocyte responses against HCV. The methods comprise obtaining peripheral blood lymphocytes (PBL) from infected and uninfected individuals and exposing (i.e., stimulating) the PBL cells with synthetic peptide or polypeptide fragments derived from a peptide region (e.g., core region (e.g., ADLMGYIPLV (Core<sub>131-140</sub>; SEQ ID NO:1) and LLALLSCLTV (Core<sub>178-187</sub>; SEQ ID NO:2)), NS3 (e.g., LLCPAGHAV (NS3<sub>1169-1177</sub>; SEQ ID NO:26) and KLVALGINAV (NS3<sub>1406-1415</sub>; SEQ ID NO:28)), NS4 (e.g., SLMAFTAAV (NS4<sub>1789-1797</sub>; SEQ ID NO:34) and LLFNILGGWV (NS4<sub>1807-1816</sub>; SEQ ID NO:35)), and NS5 (e.g., ILDSFDPLV (NS5<sub>2252-2260</sub>; SEQ ID NO:42)). The peptides DLMGYIPLV (Core<sub>131-140</sub>; SEQ ID NO:54) and QLRRHIDLLV (SEQ ID NO:55) are useful in this regard as well.

Pools of overlapping synthetic peptides randomly selected from the HCV sequence, each typically about 8 to 20 residues long, preferably 9-12 residues, can be used to stimulate the cells. Alternatively, as exemplified below in Example 1 for HLA-A2 specific CTL epitopes, peptides fitting a binding motif for CTL-directed antigens of a particular HLA class I allele (Falk et al., Nature, 351, 290-296 (1991)) were selected for testing. It is contemplated that peptides fitting the analogous binding motifs for other HLA class I alleles, such as HLA-Aw68 (Guo et al., Nature, 360, 364-366 (1992)) or HLA-B27 (Jardetzky et al., Nature, 353, 326-329 (1991)), among others, may be identified by following the methods disclosed herein, and accordingly are viewed as part of the present invention. Active peptides can be selected from pools that induce cytotoxic T lymphocyte activity. The ability of the peptides to induce specific cytotoxic activity is determined by incubating the stimulated PBL cells with autologous labeled (e.g., <sup>51</sup>Cr) target cells

08854325-051297

(such as HLA matched macrophages, T cells, fibroblasts or B lymphoblastoid cells) infected or transfected with the HCV subgenomic fragments thereof, such that the targeted antigen is synthesized endogenously by the cell (or the cell is pulsed with the peptide of interest), and measuring specific release of label.

Once a peptide having an epitopic region that stimulates a cytotoxic T lymphocyte response is identified, the MHC restriction element of the response can be determined and/or confirmed. This involves incubating the stimulated PBL or short term lines thereof with a panel of (labeled) target cells or known HLA types that have been pulsed with the peptide of interest, or appropriate controls. The HLA allele(s) of cells in the panel that are lysed by the CTL are compared to cells not lysed, and the HLA restriction element(s) for the cytotoxic T lymphocyte response to the antigen of interest is identified.

Carbone et al., J. Exp. Med., 167, 1767 (1988), have reported that stimulation with peptides may induce cytotoxic T lymphocytes with low affinity for corresponding endogenous protein, such that repetitive peptide stimulation may yield cytotoxic T lymphocytes that recognize peptide but not native antigen. As the inability of stimulated cytotoxic T lymphocytes to recognize native HCV proteins would be undesirable in the development of HCV peptide therapeutics and vaccine compositions, methods to circumvent this potential limitation are used. A sequential restimulation of cytotoxic T cells is employed in the present invention to identify and select T cells with a higher affinity for naturally processed antigen than for a synthetic peptide. Short term cytotoxic T lymphocyte lines are established by restimulating activated PBL. Cells stimulated with peptide are restimulated with peptide and recombinant or native HCV antigen, e.g., NS3 derived peptide. Cells

having activity are also stimulated with an appropriate T cell mitogen, e.g., phytohemagglutinin (PHA). The restimulated cells are provided with irradiated allogeneic PBLs as an antigen nonspecific source of T cell help, and HCV antigen. To expand selectively the population of cytotoxic T lymphocytes that recognize native HCV antigen and to establish long term lines, a sample of PBL from a patient is first stimulated with peptide and recombinant or native HCV antigen, followed by restimulation with HLA-matched B lymphoblastoid cells that stably express the corresponding HCV antigen polypeptide. The cell lines are re-confirmed for the ability to recognize endogenously synthesized antigen using autologous and allogeneic B-lymphoblastoid or other cells transfected or infected so as to produce the appropriate antigen.

Having identified different peptides of the invention that contribute to inducing anti-HCV cytotoxic T lymphocyte responses in one or more patients or HLA types, in some instances it may be desirable to join two or more peptides in a composition, either by chemical linkage or as a physical mixture. The peptides in the composition can be identical or different, and together they should provide equivalent or greater biological activity than the parent peptide(s). For example, using the methods described herein, two or more peptides may define different or overlapping cytotoxic T lymphocyte epitopes from a particular region, e.g. NS3 as in LLCPAGHAV (NS3<sub>1169-1177</sub>; SEQ ID NO:26) and KLVALGINAV (NS3<sub>1406-1415</sub>; SEQ ID NO:28), which peptides can be combined in a "cocktail" to provide enhanced immunogenicity for cytotoxic T lymphocyte responses. Moreover, suitable peptides of one region can be combined with suitable peptides of other HCV regions, from the same or different HCV protein, particularly when a second or subsequent peptide has a MHC restriction element different from the

first. The present disclosure includes HCV epitope sequences derived from Core, E, NS3, NS4, and NS5 regions.

This composition of peptides can be used effectively to broaden the immunological coverage provided by therapeutic, prophylactic, or diagnostic methods and compositions of the present invention for the benefit of a diverse population. For example, the different frequencies of HLA alleles among prevalent ethnic groups (caucasian, asian and african blacks) are shown in the following table. Therapeutic or vaccine compositions of the invention may be formulated to provide potential therapy or immunity to as high a percentage of a population as possible.

Abbreviations: EUC, European Caucasian; NAC, North American Caucasian; AFR, African blacks; JPN, Japanese. \*A28 represents the two alleles A268 and A269

The peptides of the invention can be combined via linkage to form polymers (multimers), or can be formulated in a composition without linkage, as an admixture. Where the same peptide is linked to itself, thereby forming a homopolymer, a plurality of repeating epitopic units are presented. When the peptides differ, heteropolymers with repeating units are provided, forming a cocktail of, for example, epitopes specific to different HCV subtypes, different epitopes to the same protein or gene region within a subtype, different epitopes to different proteins or gene regions within a subtype, different HLA restriction specificities, and/or

a peptide that contains T helper epitopes. In addition to covalent linkages, noncovalent linkages capable of forming intermolecular and intrastructural bonds are included.

5        Linkages for homo- or hetero-polymers or for coupling to carriers can be provided in a variety of ways. For example, cysteine residues can be added at both the amino- and carboxy-termini, where the peptides are covalently bonded via controlled oxidation of the  
10        cysteine residues. Also useful are a large number of heterobifunctional agents that generate a disulfide link at one functional group end and a peptide link at the other, including N-succidimidyl-3-(2-pyridyl-dithio) propionate (SPDP). This reagent creates a disulfide  
15        linkage between itself and a cysteine residue in one protein and an amide linkage through the amino on a lysine or other free amino group in the other. A variety of such disulfide/amide forming agents are known. See, for example, Immun. Rev., 62, 185 (1982). Other  
20        bifunctional coupling agents form a thioether rather than a disulfide linkage. Many of these thioether forming agents are commercially available (from, for example, Aldrich Chemical Company, Inc., Milwaukee, WI) and include reactive esters of 6-maleimidocaproic acid, 2  
25        bromoacetic acid, 2-iodoacetic acid, 4-(N-maleimido-methyl)cyclohexane-1-carboxylic acid and the like. The carboxyl groups can be activated by combining them with succinimide or 1-hydroxy-2-nitro-4-sulfonic acid, sodium salt. A particularly preferred coupling agent is  
30        succinimidyl-4-(n-maleimidomethyl)cyclohexane-1-carboxylate (SMCC). It will be understood that suitable linkage does not substantially interfere with either of the linked groups to function as described, e.g., as a HCV cytotoxic T cell determinant/stimulant, peptide  
35        analogs, or T helper determinant/stimulant.

In another aspect of the present invention, the peptides of the invention can be combined or coupled with other suitable peptides that present HCV T-helper cell epitopes, i.e., epitopes that stimulate T cells that cooperate in the induction of cytotoxic T cells to HCV. The T-helper cells can be either the T-helper 1 or T-helper 2 phenotype, for example.

The peptides of the invention can be prepared using any suitable means. Because of their relatively short size (generally, less than 50 amino acids, and preferably less than 20), the peptides can be synthesized in solution or on a solid support in accordance with conventional peptide synthesis techniques. Various automatic synthesizers are commercially available (for example, from Applied Biosystems) and can be used in accordance with known protocols. See, for example, Stewart and Young, Solid Phase Peptide Synthesis (2d. ed., Pierce Chemical Co., 1984); Tam et al., J. Am. Chem. Soc., 105, 6442 (1983); Merrifield, Science, 232, 341-347 (1986); and Barany and Merrifield, The Peptides (Gross and Meienhofer, eds., Academic Press, New York, 1979), 1-284.

Alternatively, suitable recombinant DNA technology may be employed for the preparation of the peptides of the present invention, wherein a nucleotide sequence that encodes a peptide of interest is inserted into an expression vector, transformed or transfected into a suitable host cell and cultivated under conditions suitable for expression. These procedures are generally known in the art, as described generally in Sambrook et al., Molecular Cloning, A Laboratory Manual (2d ed., Cold Spring Harbor Press, Cold Spring Harbor, New York, 1989), and Current Protocols in Molecular Biology (Ausubel et al., eds., John Wiley and Sons, Inc., New York, 1987), and U.S. Pat. Nos. 4,237,224, 4,273,875, 4,431,739, 4,363,877 and 4,428,941, for example. Thus, recombinant

DNA-derived proteins or peptides, which comprise one or more peptide sequences of the invention, can be used to prepare the HCV cytotoxic T cell epitopes identified herein or identified using the methods disclosed herein.

5 For example, a recombinant NS3-derived peptide of the present invention is prepared in which the NS3 amino acid sequence is altered so as to present more effectively epitopes of peptide regions described herein to stimulate a cytotoxic T lymphocyte response. By this means, a  
10 polypeptide is used that incorporates several T cell epitopes into a single polypeptide.

As the coding sequence for peptides of the length contemplated herein can be synthesized by chemical techniques, for example, the phosphotriester method of  
15 Matteucci et al., J. Am. Chem. Soc., 103, 3185 (1981), modification can be made simply by substituting the appropriate base(s) for those encoding the native peptide sequence. The coding sequence can then be provided with appropriate linkers and ligated into expression vectors  
20 commonly available in the art, and the vectors used to transform suitable hosts to produce the desired fusion protein. A number of such vectors and suitable host systems are now available. For expression of the fusion proteins, the coding sequence will be provided with  
25 operably linked start and stop codons, promoter and terminator regions and usually a replication system to provide an expression vector for expression in a suitable cellular host. For example, promoter sequences compatible with bacterial hosts are provided in plasmids  
30 containing convenient restriction sites for insertion of the desired coding sequence. The resulting expression vectors are transformed into suitable bacterial hosts. yeast or mammalian cell hosts may also be used, employing suitable vectors and control sequences.

35 Another aspect of the present invention is directed to a method of provoking an immune response to a

08354325-051297

hepatitis C viral antigen, comprising contacting a suitable cytotoxic T lymphocyte with an immune response provoking effective amount of a molecule comprising a peptide selected from the group of CTL epitopes recited hereinabove. All of the variations recited hereinabove regarding the molecule of the present invention and the polypeptide that such a molecule includes may be used in the context of the method of provoking an immune response.

Such a contact between the CTL epitope-containing molecule, which may be the CTL epitope alone or a complex of radiolabeled CTL epitope, for example, or some other CTL epitope analog as described above, and a CTL may occur in vitro. Accordingly, after having effected such a contact, after which the CTL's are stimulated with respect to the antigen with which it was placed in contact, the CTL's may then be returned to the originating host for a therapeutic purpose, which is further discussed below. A diagnostic purpose, of course, is satisfied whether the contacted cells are returned to the host or not. That purpose is to answer whether the CTL's of the host can bind the tested epitope and, if so, be stimulated by it, however configured. Indeed, the present invention contemplates various assay methods for detecting in lymphocytes of a mammal cytotoxic T cells that respond to a T cell epitope of hepatitis C virus, which is a consequence of a classic ligand-receptor binding phenomenon. Indeed, the present invention includes assays for the determination of the strength of such binding, using methods well known in the study of ligands and receptors.

A preferred embodiment of the present invention (referred to as Diagnostic 1) is directed to a method of detecting in the lymphocytes of a mammal cytotoxic T cells that respond to a particular T cell epitope of hepatitis C virus, comprising the steps of:

(a) contacting target cells with a molecule comprising at least one of the peptides selected from the group of epitopes recited hereinabove, wherein the target cells are of the same HLA class as the lymphocytes to be tested for the cytotoxic T cells; (b) contacting the lymphocytes to be tested for the cytotoxic T cells with a molecule comprising at least one of the peptides selected from the same group of epitopes listed hereinabove, or ones substantially homologous thereto, under conditions sufficient to restimulate the HCV-specific CTL to respond to appropriate target cells; and (c) determining whether the tested lymphocytes exert a cytotoxic effect on the target cells, thereby indicating the presence of CTL that recognize a T-cell epitope of HCV protein.

Another preferred embodiment (referred to as Diagnostic 2) is directed to a method of detecting in lymphocytes of a mammal CTL's that have receptors that can bind to a particular T cell epitope of HCV, comprising the steps of: (a) contacting the lymphocytes to be tested for the CTL's with a molecule comprising a suitable label and at least one of the peptides selected from the same group of epitopes listed hereinabove, or ones substantially homologous thereto, under suitable conditions of time, temperature, humidity, and salts, nutrients, and pH sufficient to restimulate the HCV-specific CTL to respond to appropriate target cells; (b) harvesting such contacted cells and washing with medium in the absence of the labeled molecule sufficient to remove any unbound labeled molecule; and (c) measuring the bound labeled molecule using suitable measuring means. Step (b) may alternatively be accomplished by lysing the cells using a hypotonic solution with or without unlabeled molecule or other means known in the art, and preparing a membrane fraction that is free of unbound labeled molecule. A suitable label used in the context of this method includes radioactive isotope

tagged molecules, wherein constituent nonradioactive atoms of the molecule have been replaced with radioactive ones, such as  $^3\text{H}$ ,  $^{14}\text{C}$ , or  $^{35}\text{S}$ , or if a benzene ring or other suitable group is included in the molecule,  $^{125}\text{I}$  can be affixed thereto. Other suitable labels include fluorescent groups such as fluorescein isothiocyanate or rhodamine isothiocyanate, that can be affixed covalently to appropriate amino acid side groups using methods well known in the art, as well as enzymes that can convert a substrate from one color to another, such as alkaline phosphatase. A suitable measuring means includes a scintillation gamma ray, or geiger counter and the like, as well as a spectrophotometer, even just a color chart for eyeball comparisons of a reaction color to published standards that indicate certain concentrations of bound ligand, i.e., peptide.

Specific methods used for procuring the cells from a patient, culturing them, and determining the existence and/or extent of cytotoxicity of a given population of cells are well known in the art, one exemplification of which is recited below in Example 2. It is also contemplated that the contacting of host lymphocytes occurring in the aforescribed diagnostic procedures may take place in vivo on in vitro, and if in vivo, then Diagnostic 1, step (a) and (c) take place in vitro; and Diagnostic 2, (step (b) and (c) also take place in vitro. Accordingly, the present invention provides for the detection of human CTL, for instance in blood or other tissues of patients known or suspected to be infected with HCV, by appropriately adapting methods known for detecting other human CTL. See, for instance, Clerici, et al., J. Imm., 146, 2214-2219 (1991). Additionally, the present invention provides a method to detect cells having receptors specific to the peptides of the present invention.

The assay of this invention is useful for determining whether the immune system of a mammal has been provoked by the above recited epitopes of HCV, thereby to determine whether the occurrence and magnitude of such a response can be correlated with either the occurrence of HCV infection (i.e., for diagnosis) or the severity of the pathogenic effect of the virus (i.e., as a prognostic indicator).

Accordingly, a peptide of the invention may be used to determine the susceptibility of a particular individual to a treatment regimen that employs the peptide or related peptides, and thus may be helpful in modifying an existing treatment protocol or in determining a prognosis for an affected individual. In addition, the peptides may also be used to predict which individuals will be at substantial risk for developing chronic ~~HBV~~<sup>HCV</sup> infection.

The contacting between the molecule of the present invention, in any of its various forms, and the CTL that has been described above as an in vitro procedure also preferably occurs in a mammal, including humans and other mammalian species. Introduction of the CTL epitope, in one of its hitherto described forms, may be usefully provided to an individual afflicted with an acute or chronic form of infection, or with no infection at all, in which case the introduction would have a prophylactic effect.

A preferred preparation of the CTL epitope, in whatever form, or, for that matter, of the in vitro stimulated CTL's intended to be reintroduced to a host, is as a pharmaceutical composition. In particular, a pharmaceutical composition of the present invention is comprised of a molecule that includes a polypeptide having substantial homology with a CTL epitope selected from the group of epitopes listed hereinabove, or the

00004325-051297

polypeptide itself, and a pharmaceutically acceptable carrier.

One skilled in the art will appreciate that suitable methods of administering a compound to a mammal for the treatment of an acute or chronic case of HCV hepatitis, for example, which would be useful in the method of the present invention, are available. Although more than one route can be used to administer a particular compound, a particular route can provide a more immediate and more effective reaction than another route. Accordingly, the described methods provided herein are merely exemplary and are in no way limiting.

Generally, the peptides of the present invention as described above will be administered in a pharmaceutical composition to an individual already infected with HCV. Those in the incubation phase or the acute phase of infection can be treated with the immunogenic peptides separately or in conjunction with other treatments, as appropriate. In therapeutic applications, compositions are administered to a patient in an amount sufficient to elicit an effective cytotoxic T lymphocyte response to HCV and to cure or at least partially arrest its symptoms and/or complications. An amount adequate to accomplish this is defined as a "therapeutically or prophylactically effective dose" which is also an "immune response provoking amount." Amounts effective for a therapeutic or prophylactic use will depend on, e.g., the stage and severity of the disease being treated, the age, weight, and general state of health of the patient, and the judgment of the prescribing physician. The size of the dose will also be determined by the peptide composition, method of administration, timing and frequency of administration as well as the existence, nature, and extent of any adverse side-effects that might accompany the administration of a particular compound or stimulated CTL's and the desired physiological effect. It will be

appreciated by one of skill in the art that various conditions or disease states may require prolonged treatment involving multiple administrations.

Suitable doses and dosage regimens can be determined by conventional range-finding techniques known to those of ordinary skill in the art. Generally, treatment is initiated with smaller dosages that are less than the optimum dose of the compound. Thereafter, the dosage is increased by small increments until the optimum effect under the circumstances is reached. The present inventive method typically will involve the administration of about 0.1  $\mu$ g to about 50 mg of one or more of the compounds described above per kg body weight of the individual. For a 70 kg patient, dosages of from about 10  $\mu$ g to about 100 mg of peptide would be more commonly used, followed by booster dosages from about 1  $\mu$ g to about 1 mg of peptide over weeks to months, depending on a patient's CTL response, as determined by measuring HCV-specific CTL activity in PBLs obtained from the patient. For the reintroduction of stimulated CTL's, which were derived from the patient, typically a dose would range upward from 1% of the number of cells removed up to all of them.

It must be kept in mind that the peptides and compositions of the present invention may generally be employed in serious disease states, that is, life-threatening or potentially life threatening situations. In such cases, in view of the minimization of extraneous substances and the relative nontoxic nature of the peptides, it is possible and may be felt desirable by the treating physician to administer substantial excesses of these peptide compositions.

Single or multiple administrations of the compositions can be carried out with dose levels and pattern being selected by the treating physician. In any event, the pharmaceutical formulations should provide a

quantity of cytotoxic T-lymphocyte stimulatory peptides of the invention sufficient to effectively treat the patient.

For therapeutic use, administration should begin at the first sign of HCV infection or shortly after diagnosis in cases of acute infection, and continue until at least symptoms are substantially abated and for a period thereafter. In well established and chronic cases, loading doses followed by maintenance or booster doses may be required. The elicitation of an effective cytotoxic T lymphocyte response to HCV during treatment of acute hepatitis will minimize the possibility of subsequent development of chronic hepatitis, HCV carrier stage, and ensuing hepatocellular carcinoma.

Treatment of an infected individual with the compositions of the invention may hasten resolution of the infection in acutely infected individuals, the majority of whom are capable of resolving the infection naturally. For those individuals susceptible (or predisposed) to developing chronic infection, the compositions are particularly useful in methods for preventing the evolution from acute to chronic infection. Where the susceptible individuals are identified prior to or during infection, for instance by using the diagnostic procedures described herein, the composition can be targeted to them, minimizing need for administration to a larger population.

The peptide compositions can also be used for the treatment of chronic hepatitis and to stimulate the immune system of carriers to substantially reduce or even eliminate virus-infected cells. Those with chronic hepatitis can be identified as testing positive for virus from about 3-6 months after infection. As individuals may develop chronic HCV infection because of an inadequate (or absent) cytotoxic T lymphocyte response during the acute phase of their infection, it is

important to provide an amount of immuno-potentiating peptide in a formulation and mode of administration sufficient to stimulate effectively a cytotoxic T cell response. Thus, for treatment and/or prevention of chronic hepatitis, a representative dose is in the range of about 1  $\mu$ g to 1,000 mg, preferably about 5  $\mu$ g to 100 mg for a 70 kg patient per dose. Administration should continue until at least clinical symptoms or laboratory indicators indicate that the HCV infection has been eliminated or substantially abated and for a period thereafter. Immunizing doses followed by maintenance or booster doses at established intervals, e.g., from one to four weeks, may be required, possibly for a prolonged period of time, as necessary to resolve the infection. For the treatment of chronic and carrier HCV infection, it may be desirable to combine the CTL peptides with peptides or proteins that induce immune response to a combination of HCV antigens.

The pharmaceutical compositions for therapeutic treatment are intended for parenteral, topical, oral or local administration and generally comprise a pharmaceutically acceptable carrier and an amount of the active ingredient sufficient to reverse or prevent the bad effects of acute or chronic HCV infection, for example. The carrier may be any of those conventionally used and is limited only by chemico-physical considerations, such as solubility and lack of reactivity with the compound, and by the route of administration.

Examples of pharmaceutically acceptable acid addition salts for use in the present inventive pharmaceutical composition include those derived from mineral acids, such as hydrochloric, hydrobromic, phosphoric, metaphosphoric, nitric and sulfuric acids, and organic acids, such as tartaric, acetic, citric, malic, lactic, fumaric, benzoic, glycolic, gluconic,

succinic, p-toluenesulphonic acids, and arylsulphonic, for example.

The pharmaceutically acceptable excipients described herein, for example, vehicles, adjuvants, carriers or  
5 diluents, are well-known to those who are skilled in the art and are readily available to the public. It is preferred that the pharmaceutically acceptable carrier be one that is chemically inert to the active compounds and one that has no detrimental side effects or toxicity  
10 under the conditions of use.

The choice of excipient will be determined in part by the particular epitope and epitope formulation chosen, as well as by the particular method used to administer the composition. Accordingly, there is a wide variety of  
15 suitable formulations of the pharmaceutical composition of the present invention.

The following formulations for oral, aerosol, parenteral, subcutaneous, intravenous, intramuscular, interperitoneal, rectal, and vaginal administration are  
20 merely exemplary and are in no way limiting.

Preferably, the pharmaceutical compositions are administered parenterally, e.g., intravenously, subcutaneously, intradermally, or intramuscularly. Thus, the invention provides compositions for parenteral  
25 administration that comprise a solution of the cytotoxic T-lymphocyte stimulatory peptides dissolved or suspended in an acceptable carrier suitable for parenteral administration, including aqueous and non-aqueous, isotonic sterile injection solutions.

Overall, the requirements for effective  
30 pharmaceutical carriers for parenteral compositions are well known to those of ordinary skill in the art. See Pharmaceutics and Pharmacy Practice, J.B. Lippincott Company, Philadelphia, PA, Banker and Chalmers, eds.,  
35 pages 238-250, (1982), and ASHP Handbook on Injectable Drugs, Toissel, 4th ed., pages 622-630 (1986). Such

0554825 051297

solutions can contain anti-oxidants, buffers, bacteriostats, and solutes that render the formulation isotonic with the blood of the intended recipient, and aqueous and non-aqueous sterile suspensions that can include suspending agents, solubilizers, thickening agents, stabilizers, and preservatives. The compound may be administered in a physiologically acceptable diluent in a pharmaceutical carrier, such as a sterile liquid or mixture of liquids, including water, saline, aqueous dextrose and related sugar solutions, an alcohol, such as ethanol, isopropanol, or hexadecyl alcohol, glycols, such as propylene glycol or polyethylene glycol, dimethylsulfoxide, glycerol ketals, such as 2,2-dimethyl-1,3-dioxolane-4-methanol, ethers, such as poly(ethyleneglycol) 400, an oil, a fatty acid, a fatty acid ester or glyceride, or an acetylated fatty acid glyceride with or without the addition of a pharmaceutically acceptable surfactant, such as a soap or a detergent, suspending agent, such as pectin, carbomers, methylcellulose, hydroxypropylmethylcellulose, or carboxymethylcellulose, or emulsifying agents and other pharmaceutical adjuvants.

Oils useful in parenteral formulations include petroleum, animal, vegetable, or synthetic oils. Specific examples of oils useful in such formulations include peanut, soybean, sesame, cottonseed, corn, olive, petrolatum, and mineral. Suitable fatty acids for use in parenteral formulations include oleic acid, stearic acid, and isostearic acid. Ethyl oleate and isopropyl myristate are examples of suitable fatty acid esters.

Suitable soaps for use in parenteral formulations include fatty alkali metal, ammonium, and triethanolamine salts, and suitable detergents include (a) cationic detergents such as, for example, dimethyl dialkyl ammonium halides, and alkyl pyridinium halides, (b) anionic detergents such as, for example, alkyl, aryl, and

olefin sulfonates, alkyl, olefin, ether, and monoglyceride sulfates, and sulfosuccinates, (c) nonionic detergents such as, for example, fatty amine oxides, fatty acid alkanolamides, and

- 5 polyoxyethylenepolypropylene copolymers, (d) amphoteric detergents such as, for example, alkyl- $\beta$ -aminopropionates, and 2-alkyl-imidazoline quaternary ammonium salts, and (e) mixtures thereof.

The parenteral formulations typically will contain  
10 from about 0.5 to about 25% by weight of the active ingredient in solution. Preservatives and buffers may be used. In order to minimize or eliminate irritation at the site of injection, such compositions may contain one or more nonionic surfactants having a  
15 hydrophile-lipophile balance (HLB) of from about 12 to about 17. The quantity of surfactant in such formulations will typically range from about 5 to about 15% by weight. Suitable surfactants include polyethylene sorbitan fatty acid esters, such as sorbitan monooleate and the high molecular weight adducts of ethylene oxide  
20 with a hydrophobic base, formed by the condensation of propylene oxide with propylene glycol. The parenteral formulations can be presented in unit-dose or multi-dose sealed containers, such as ampules and vials, and can be  
25 stored in a freeze-dried (lyophilized) condition requiring only the addition of the sterile liquid excipient, for example, water, for injections, immediately prior to use. Extemporaneous injection solutions and suspensions can be prepared from sterile  
30 powders, granules, and tablets of the kind previously described.

Topical formulations, including those that are useful for transdermal drug release, are well-known to those of skill in the art and are suitable in the context  
35 of the present invention for application to skin.

Formulations suitable for oral administration require extra considerations considering the peptidyl nature of the epitopes and the likely breakdown thereof if such compounds are administered orally without protecting them from the digestive secretions of the gastrointestinal tract. Such a formulation can consist of (a) liquid solutions, such as an effective amount of the compound dissolved in diluents, such as water, saline, or orange juice; (b) capsules, sachets, tablets, lozenges, and troches, each containing a predetermined amount of the active ingredient, as solids or granules; (c) powders; (d) suspensions in an appropriate liquid; and (e) suitable emulsions. Liquid formulations may include diluents, such as water and alcohols, for example, ethanol, benzyl alcohol, and the polyethylene alcohols, either with or without the addition of a pharmaceutically acceptable surfactant, suspending agent, or emulsifying agent. Capsule forms can be of the ordinary hard- or soft-shelled gelatin type containing, for example, surfactants, lubricants, and inert fillers, such as lactose, sucrose, calcium phosphate, and corn starch. Tablet forms can include one or more of lactose, sucrose, mannitol, corn starch, potato starch, alginic acid, microcrystalline cellulose, acacia, gelatin, guar gum, colloidal silicon dioxide, croscarmellose sodium, talc, magnesium stearate, calcium stearate, zinc stearate, stearic acid, and other excipients, colorants, diluents, buffering agents, disintegrating agents, moistening agents, preservatives, flavoring agents, and pharmacologically compatible excipients. Lozenge forms can comprise the active ingredient in a flavor, usually sucrose and acacia or tragacanth, as well as pastilles comprising the active ingredient in an inert base, such as gelatin and glycerin, or sucrose and acacia, emulsions, gels, and the like containing, in addition to

the active ingredient, such excipients as are known in the art.

08854822 091297

The molecules and/or peptides of the present invention, alone or in combination with other suitable components, can be made into aerosol formulations to be administered via inhalation. For aerosol administration, the cytotoxic T-lymphocyte stimulatory peptides are preferably supplied in finely divided form along with a surfactant and propellant. Typical percentages of peptides are 0.01%-20% by weight, preferably 1%-10%. The surfactant must, of course, be nontoxic, and preferably soluble in the propellant. Representative of such agents are the esters or partial esters of fatty acids containing from 6 to 22 carbon atoms, such as caproic, octanoic, lauric, palmitic, stearic, linoleic, linolenic, olesteric and oleic acids with an aliphatic polyhydric alcohol or its cyclic anhydride. Mixed esters, such as mixed or natural glycerides may be employed. The surfactant may constitute 0.1%-20% by weight of the composition, preferably 0.25-5%. The balance of the composition is ordinarily propellant. A carrier can also be included as desired, e.g., lecithin for intranasal delivery. These aerosol formulations can be placed into acceptable pressurized propellants, such as dichlorodifluoromethane, propane, nitrogen, and the like. They also may be formulated as pharmaceuticals for non-pressured preparations, such as in a nebulizer or an atomizer. Such spray formulations may be used to spray mucosa.

Additionally, the compounds and polymers useful in the present inventive methods may be made into suppositories by mixing with a variety of bases, such as emulsifying bases or water-soluble bases. Formulations suitable for vaginal administration may be presented as pessaries, tampons, creams, gels, pastes, foams, or spray formulas containing, in addition to the active

ingredient, such carriers as are known in the art to be appropriate.

In some embodiments, it may be desirable to include in the pharmaceutical composition at least one component that primes CTL generally. Lipids have been identified that are capable of priming CTL in vivo against viral antigens, e.g., ~~tripalmitoyl-S-glycerol~~ <sup>trioleoyl-S-glycerol</sup> ~~serine~~ <sup>serine</sup> (P<sub>3</sub>CSS), which can effectively prime virus specific cytotoxic T lymphocytes when covalently attached to an appropriate peptide. See, Deres et al., Nature, 342, 561-564 (1989). Peptides of the present invention can be coupled to P<sub>3</sub>CSS, for example and the lipopeptide administered to an individual to specifically prime a cytotoxic T lymphocyte response to HCV. Further, as the induction of neutralizing antibodies can also be primed with P<sub>3</sub>CSS conjugated to a peptide that displays an appropriate epitope, e.g., certain NS3 epitopes, the two compositions can be combined to elicit more effectively both humoral and cell-mediated responses to HCV infection.

The concentration of cytotoxic T-lymphocyte stimulatory peptides of the present invention in the pharmaceutical formulations can vary widely, i.e., from less than about 1%, usually at or at least about 10% to as much as 20 to 50% or more by weight, and will be selected primarily by fluid volumes, viscosities, etc., in accordance with the particular mode of administration selected.

Thus, a typical pharmaceutical composition for intravenous infusion could be made up to contain 250 ml of sterile Ringer's solution, and 100 mg of peptide. Actual methods for preparing parenterally administrable compounds will be known or apparent to those skilled in the art and are described in more detail in, for example, Remington's Pharmaceutical Science (17th ed., Mack Publishing Company, Easton, PA, 1985).

It will be appreciated by one of ordinary skill in the art that, in addition to the aforescribed pharmaceutical compositions, the compounds of the present inventive method may be formulated as inclusion  
5 complexes, such as cyclodextrin inclusion complexes, or liposomes. Liposomes serve to target the peptides to a particular tissue, such as lymphoid tissue or HCV-infected hepatic cells. Liposomes can also be used to increase the half-life of the peptide composition.  
10 Liposomes useful in the present invention include emulsions, foams, micelles, insoluble monolayers, liquid crystals, phospholipid dispersions, lamellar layers and the like. In these preparations the peptide to be delivered is incorporated as part of a liposome, alone or  
15 in conjunction with a molecule which binds to, e.g., a receptor, prevalent among lymphoid cells, such as monoclonal antibodies which bind to the CD45 antigen, or with other therapeutic or immunogenic compositions. Thus, liposomes filled with a desired peptide of the  
20 invention can be directed to the site of lymphoid or hepatic cells, where the liposomes then deliver the selected therapeutic/immunogenic peptide compositions. Liposomes for use in the invention are formed from standard vesicle-forming lipids, which generally include  
25 neutral and negatively charged phospholipids and a sterol, such as cholesterol. The selection of lipids is generally guided by consideration of, for example, liposome size and stability of the liposomes in the blood stream. A variety of methods are available for preparing  
30 liposomes, as described in, for example, Szoka et al., Ann. Rev. Biophys. Bioeng., 9, 467 (1980), and U.S. Patent Nos. 4,235,871, 4,501,728, 4,837,028 and 5,019,369. For targeting to the immune cells, a ligand to be incorporated into the liposome can include, for  
35 example, antibodies or fragments thereof specific for cell surface determinants of the desired immune system

05034325-051247

cells. A liposome suspension containing a peptide may be administered intravenously, locally, topically, etc. in a dose that varies according to the mode of administration, the peptide being delivered, the stage of disease being treated, etc.

In another aspect the present invention is directed to vaccines that contain as an active ingredient an immunogenically effective amount of a cytotoxic T-lymphocyte stimulating peptide, as described herein. The peptide(s) may be introduced into a host, including humans, linked to its own carrier or as a homopolymer or heteropolymer of active peptide units. Such a polymer has the advantage of increased immunological reaction and, where different peptides are used to make up the polymer, the additional ability to induce antibodies and/or cytotoxic T cells that react with different antigenic determinants of HCV. Useful carriers are well known in the art, and include, e.g., keyhole limpet hemocyanin, thyroglobulin, albumins such as human serum albumin, tetanus toxoid, polyamino acids such as poly(D-lysine:D-glutamic acid), and the like. The vaccines can also contain a physiologically tolerable (acceptable) diluent such as water, phosphate buffered saline, or saline, and further typically include an adjuvant. Adjuvants such as incomplete Freund's adjuvant, aluminum phosphate, aluminum hydroxide, or alum or materials well known in the art. And, as mentioned above, cytotoxic T lymphocyte responses can be primed by conjugating peptides of the invention to lipids, such as P<sub>3</sub>CSS. Upon immunization with a peptide composition as described herein, via ~~injection~~ *infection*, aerosol, oral, transdermal or other route, the immune system of the host responds to the vaccine by producing large amounts of cytotoxic T-lymphocytes specific for HCV antigen, and the host becomes at least partially immune to HCV infection, or resistant to developing chronic HCV infection.

B

30

35

both of the B and C hepatitis viruses. For examples of HBV vaccines that can be formulated with the HCV-directed peptides of the present invention, see generally, EP 154,902 and EP 291,586, and U.S. Patent Nos. 4,565,697, 4,624,918, 4,599,230, 4,599,231, 4,803,164, 4,882,145, 4,977,092, 5,017,558 and 5,019,386. The vaccines can be combined and administered concurrently, or as separate preparations.

For therapeutic or immunization purposes, the peptides of the invention can also be expressed by attenuated viral hosts, such as vaccinia. This approach involves the use of vaccinia virus as a vector to express nucleotide sequences that encode the HCV peptides of the invention. Upon introduction into an acutely or chronically HCV-infected host or into a non-infected host, the recombinant vaccinia virus expresses the HCV peptide and thereby elicits a host cytotoxic T lymphocyte response to HCV. Vaccinia vectors and methods useful in immunization protocols are described in, e.g., U.S. Patent No. 4,722,848. Another vector is BCG (bacille Calmette Guerin). BCG vectors are described in Stover et al., Nature, 351, 456-460 (1991). A wide variety of other vectors useful for therapeutic administration or immunization of the peptides of the invention, e.g., Salmonella typhi vectors and the like, will be apparent to those skilled in the art from the description herein.

The compositions and methods of the claimed invention may be employed for ex vivo therapy, wherein, as described briefly above, a portion of a patient's lymphocytes are removed, challenged with a stimulating dose of a peptide of the present invention, and the resultant stimulated CTL's are returned to the patient. Accordingly, in more detail, ex vivo therapy as used herein concerns the therapeutic or immunogenic manipulations that are performed outside the body on lymphocytes or other target cells that have been removed

from a patient. Such cells are then cultured in vitro with high doses of the subject peptides, providing a stimulatory concentration of peptide in the cell medium far in excess of levels that could be accomplished or tolerated by the patient. Following treatment to stimulate the CTLs, the cells are returned to the host, thereby treating the HCV infection. The host's cells may also be exposed to vectors that carry genes encoding the peptides, as described above. Once transfected with the vectors, the cells may be propagated in vitro or returned to the patient. The cells that are propagated in vitro may be returned to the patient after reaching a predetermined cell density.

In one method, in vitro CTL responses to HCV are induced by incubating in tissue culture a patient's CTL precursor cells (CTLp) together with a source of antigen-presenting cells (APC) and the appropriate immunogenic peptide. After an appropriate incubation time (typically 1-4 weeks), in which the CTLp are activated and mature and expand into effector CTL, the cells are infused back into the patient, where they will destroy their specific target cell (a HCV infected cell). To optimize the in vitro conditions for the generation of specific cytotoxic T cells, the culture of stimulator cells is typically maintained in an appropriate serum-free medium. Peripheral blood lymphocytes are isolated conveniently following simple venipuncture or leukapheresis of normal donors or patients and used as the responder cell sources of CTLp. In one embodiment, the appropriate APC's are incubated with about 10-100  $\mu$ M of peptide in serum-free media for four hours under appropriate culture conditions. The peptide-loaded APC are then incubated with the responder cell populations in vitro for 5 to 10 days under optimized culture conditions.

Positive CTL activation can be determined by assaying the cultures for the presence of CTLs that kill

radiolabeled target cells, both specific peptide-pulsed targets as well as target cells expressing endogenously processed form of HCV antigen as further discussed below. Specifically, the MHC restriction of the CTL of a patient  
5 can be determined by a number of methods known in the art. For instance, CTL restriction can be determined by testing against different peptide target cells expressing appropriate or inappropriate human MHC class I. The peptides that test positive in the MHC binding assays and  
10 give rise to specific CTL responses are identified as immunogenic peptides.

The induction of CTL in vitro requires the specific recognition of peptides that are bound to allele specific MHC class I molecules on APC. Peptide loading of empty  
15 major histocompatibility complex molecules on cells allows the induction of primary CTL responses. Because mutant cell lines do not exist for every MHC allele, it may be advantageous to use a technique to remove endogenous MHC-associated peptides from the surface of  
20 APC, followed by loading the resulting empty MHC molecules with the immunogenic peptides of interest. The use of non-transformed, non-infected cells, and preferably, autologous cells of patients as APC is desirable for the design of CTL induction protocols  
25 directed towards development of ex vivo CTL therapies. Typically, prior to incubation of the APCs with the CTLp to be activated, an amount of antigenic peptide is added to the APC or stimulator cell culture, of sufficient quantity to become loaded onto the human Class I  
30 molecules to be expressed on the surface of the APCs. Resting or precursor CTLs are then incubated in culture with the appropriate APCs for a time period sufficient to activate the CTLs. Preferably, the CTLs are activated in an antigen-specific manner. The ratio of resting or  
35 precursor CTLs to APCs may vary from individual to individual and may further depend upon variables such as

the amenability of an individual's lymphocytes to culturing conditions and the nature and severity of the disease condition or other condition for which the described treatment modality is used. Preferably, however, the CTL:APC ratio is in the range of about 30:1 to 300:1. The CTL/APC may be maintained for as long a time as is necessary to stimulate a therapeutically useable or effective number of CTL.

Activated CTL may be effectively separated from the APC using one of a variety of known methods. For example, monoclonal antibodies specific for the APCs, for the peptides loaded onto the stimulator cells, or for the CTL (or a segment thereof) may be utilized to bind their appropriate complementary ligand. Antibody-tagged molecules may then be extracted from the admixture via appropriate means, e.g., via well-known immunoprecipitation or immunoassay methods.

Effective, cytotoxic amounts of the activated CTLs can vary between in vitro and in vivo uses, as well as with the amount and type of cells that are the ultimate target of these killer cells. The amount will also vary depending on the condition of the patient and should be determined via consideration of all appropriate factors by the practitioner. Preferably, however, about  $1 \times 10^6$  to about  $1 \times 10^{12}$ , more preferably about  $1 \times 10^8$  to about  $1 \times 10^{11}$ , and even more preferably, about  $1 \times 10^9$  to about  $1 \times 10^{10}$  activated CD8+ cells are utilized for adult humans, compared to about  $5 \times 10^6$  to about  $5 \times 10^7$  cells used in mice.

Methods of reintroducing cellular components are known in the art and include procedures such as those exemplified in U.S. Patent No. 4,844,893 to Honsik, et al. and U.S. Patent No. 4,690,915 to Rosenberg. For example, administration of activated CTLs via intravenous infusion is typically appropriate.

The following examples further illustrate the present invention but, of course, should not be construed as in any way limiting its scope.

5

#### Example 1

This example illustrates the identification of peptides that were tested for capability to induce HCV specific responses.

The published HCV-1 amino acid sequence (Choo et al., Proc. Natl. Acad. Sci. USA, 88, 2451-2455 (1991)) was scanned for the presence of the HLA-A2.1 binding motif XLXXXXXXV or XLXXXXXXV, which sequence is a necessary but not sufficient characteristic for class I restricted CTL stimulation. Falk et al., Nature, 351, 290-296 (1991). From this scan, 53 peptides of 9 or 10 amino acid residues each were identified as putative CTL stimulators. The identified sequences were synthesized by Chiron Mimotopes (Clayton, Australia). The 53 peptides are listed hereinbelow, wherein the single-letter code for amino acids is used: A, Ala; C, Cys; D, Asp; E, Glu; F, Phe; G, Gly; H, His; I, Ile; K, Lys; L, Leu; M, Met; N, Asp; P, Pro; Q, Gln; R, Arg; S. Ser; T, Thr; V, Val; W, Trp; Y, Tyr. The peptides marked with a dagger (†) were found to represent a CTL epitope, using the assay disclosed in Example 2. Information regarding the region of the HCV genome, the amino acid coordinates, and the sequence for each of the 53 selected peptides is included, as follows:

In summary, the HCV peptide sequences that satisfy  
 at least one of the HLA-A2.1 binding motifs recited above  
 include two peptides from the core region, two from E1,  
 six from E2/NS1, nine from NS2, nine from NS3, ten from  
 NS4 and 15 from NS5 of the HCV genome. Additionally, the  
 peptide sequence marked with an asterisk (\*; SEQ ID NO:1)  
 was found to be more potent in the cytotoxicity assay  
 described below in Example 2 than the same sequence  
 without alanine 131.

#### Example 2

This example sets forth methods used to identify  
 whether a particular polypeptide was able to induce a  
 HCV-specific response in cytotoxic T lymphocytes.

Peripheral blood mononuclear cells ("PBMC") taken  
 from patients afflicted with chronic hepatitis C  
 infection were used to assay CTL-inducing activity of the  
 identified polypeptides. Eight patients were identified  
 who were HLA-A2 positive, as determined by standard micro  
 cytotoxicity tests using HLA typing trays (One Lambda,

Canoga Park, CA). Each of these patients had chronic hepatitis C infection based on standard clinical parameters and confirmed by liver biopsy, where chronic active hepatitis ("CAH") was in evidence with or without cirrhosis ("C"). Serological assays using the second-generation (c200/c22-3) Ortho HCV ELISA test system (Ortho Diagnostics, Inc., Raritan, NJ) were conducted as well. The presence of serum HCV RNA was also detected with a "nested" cDNA polymerase chain reaction assay with primers selected from the 5' NC region and subsequent hybridization using an internal probe, as described by Bukh et al., Proc. Natl. Acad. Sci. USA, 89, 187-191 (1992).

#### Characteristics of Subject Studied

	<u>Subject (Sex)</u>	<u>HLA</u>	<u>ALT</u>	<u>HCV-PCR</u>	<u>Liver Biopsy</u>
20	C-1 (m)	A2, B44, cw3	226	pos.	CAH <sup>+</sup> C
	C-2 (f)	A2, A31, B7, B67, Cw7	99	pos.	CAH
25	C-3 (m)	A2, A3, B44, Cw7	155	pos.	CAH
	C-4 (m)	A2, A30, Bw48, Bw64, Cw3	79	pos.	CAH
	C-5 (f)	A2, A3, B65, B75, Cw1, Cw4	97	pos.	CAH
30	C-6 (f)	A2, A24, B38, B60, Cw3	190	pos.	CAH
	H-1 (m)	A2, A1, B8, B44, Cw5, Cw7	nl	pos.	nd <sup>□</sup>
35	H-2 (f)	A2, A68, B7801, Cw6	nl	pos.	nd <sup>^</sup>

□ This subject had no history of hepatitis and had normal liver enzymes; no biopsy was performed.

^ This subject had an episode of acute hepatitis C three months previously; no biopsy was performed.

PBMC from all eight HLA-A2 positive subjects were stimulated individually with the entire panel of 53 peptides, and cultures were tested after initial expansion for peptide specific CTL activity, using the following procedures:

Stimulation of PBMC with synthetic peptides and tetanus toxoid. PBMC from subjects were separated on Ficoll-Hypaque density gradients (Sigma, St. Louis, MO), washed three times in Hanks balanced salt solution (HBSS) (Gibco, Grand Island, NY), resuspended in RPMI 1640 medium (Gibco, Grand Island, NY) supplemented with L-glutamine (2 mM), gentamicin (10 µg/ml), penicillin (50 U/ml), streptomycin (50 µg/ml), and HEPES (5 mM) containing 10% heat inactivated human AB serum (complete medium) and plated in 24 well plates at  $4 \times 10^6$  cells/well. The synthetic peptides described in Example 1 were lyophilized and subsequently reconstituted at 20 mg/ml in DMSO (Malinckrodt, Paris, KY) and diluted to 1 mg/ml with RPMI 1640 medium (Gibco, Grand Island, NY).

The reconstituted synthetic peptides were then added to the cell cultures at a final concentration of 10 µg/ml. Tetanus toxoid was added at 1 µg/ml during the first week of stimulation. At day 3, 1 ml of complete medium supplemented with rIL-2 (Hoffman-La Roche, Nutley, N.Y.) at 10 U/ml final concentration was added in each well. On day 7, the cultures were restimulated with peptide, rIL-2 and irradiated (3000 rads) autologous feeder cells; the cultured PBMC were tested for CTL activity on day 14. Selected cultures that displayed peptide specific cytolytic activity (see cytotoxicity assay description below) were expanded by weekly restimulation with  $1 \times 10^6$  irradiated (3000 rads) autologous PBMC in 1 ml of complete medium containing 1 µg/ml peptide and 20 U/ml IL-1.

Generation of HCV specific CTL clones. CTL lines were cloned at 0.3, 1, 10, and 100 cells per well and

then subcloned at 0.3 or 1 cell per well in 96 well microtiter plates. The cells were plated in the presence of peptide (1  $\mu\text{g/ml}$ ), PHA (1  $\mu\text{g/ml}$ ), rIL-2 (20 U/ml), irradiated (3000 rads) allogeneic PBMC ( $10^5$  cells/well).

5 HCV specific clones were restimulated in a 24 well plate as described above.

Target Cells. Allogeneic and autologous EBV-transformed B lymphoblastoid cell lines (EBV-BCL) were either purchased from The American Society for  
10 Histocompatibility and Immunogenetics (Boston, ~~MA~~ <sup>MA</sup> or established from our own pool of patients and normal donors. The most commonly used target cell line (JY) is HLA-A2, B7 and Cw7 positive. The cells were maintained in RPMI 1640 supplemented with L-glutamine (2 mM),  
15 gentamicin (10  $\mu\text{g/ml}$ ), penicillin (50 U/ml), streptomycin (50  $\mu\text{g/ml}$ ), HEPES (5 mM), and 10% (vol/vol) heat inactivated fetal calf serum ("FCS"; Gibco, Grand Island, NY). Short term lines of autologous PBMC blasts were produced by stimulating peripheral blood PBMC with PHA at  
20 1  $\mu\text{g/ml}$  in the RPMI 1640 supplemented with L-glutamine (2 mM), gentamicin (10  $\mu\text{g/ml}$ ), penicillin (50 U/ml), streptomycin (50  $\mu\text{g/ml}$ ). HEPES (5 mM). 10% (vol/vol) heat inactivated FCS, and 10 U/ml rIL-2 for 7 days before use as target cells.

25 Recombinant expression vectors. Recombinant vaccinia viruses expressing HCV-1 derived sequences were provided by Dr. M. Houghton (Chiron Corporation, Emeryville, CA). The constructs used express HCV-1 core/E1 (aa 1-339) and E2/NS2/NS3 (aa 364-1619),  
30 respectively.

Generation of recombinant vaccinia viruses was done according to standard procedures as described by Cheng et al., J. Virol., 60, 337-344 (1986). Vaccinia infected targets were prepared by infection of  $1 \times 10^6$  cells at 10  
35 to 100 multiplicity of infection ("MOI") on a rocking

08854322 151297

plate at room temperature for one hour, followed by a single wash and overnight incubation at 37°C.

Cytotoxicity Assay. Target cells consisted of allogeneic HLA matched and mismatched EBV-BCL incubated overnight with synthetic peptides at 10 µg/ml. Target cells were labeled with 100 µCi of <sup>51</sup>Cr (Amersham, Arlington Heights, IL) for one hour and washed three times with HBSS. Cytolytic activity was determined in a standard 4 hour <sup>51</sup>Cr-release assay using U-bottom 96 well plates containing 5000 targets per well. All assays were performed in duplicate. Percent cytotoxicity was determined from the formula:  $100 \times [( \text{experimental release} - \text{spontaneous release} ) / ( \text{maximum release} - \text{spontaneous release} )]$ . Maximum release was determined by lysis of targets by detergent (1% Triton X-100 Sigma). Spontaneous release was less than 25% of maximal release in all assays.

A difference in the specific lysis of peptide pulsed target cells and nonpulsed target cells of 15% at an effector to target cell ratio of 40 to 80/1 in the initial CTL assay performed after 2 weeks of culture was considered to represent a positive CTL response and was confirmed by retesting after additional rounds of restimulation and subsequent cloning.

Flow Cytometry Analysis. Cells to be analyzed ( $0.5 \times 10^6$ ) were washed once in PBS and then incubated with fluorescent probe-conjugated anti-CD4 and anti-CD8 monoclonal antibody (leu3a. Leu2a) and similarly labeled control antibody (Becton Dickinson & Co.). After a 30-min incubation at 4°C, cells were washed in PBS with 5% BSA and analyzed with a FACScan® flow cytometer (Becton Dickinson & Co.).

### Example 3

This example illustrates results of studies that demonstrate HCV-specific responses in cytotoxic T

lymphocytes by particular polypeptides and that characterize cytotoxic T lymphocyte lines and clones so identified.

CTL response to 7 epitopes in 4 of 8 patients. As  
5 described in Example 2, PBMC were stimulated with each of  
the panel of 53 peptides and the cultures were tested  
after initial in vitro expansion for peptide specific CTL  
activity. A difference in the specific lysis of peptide  
10 pulsed target cells and nonpulsed target cells of 15% at  
an effector to target cell ratio of 40/1 to 1/80 was  
considered to represent a positive CTL response and was  
confirmed by additional rounds of restimulation and  
subsequent cloning. Figure 1 demonstrates the percentage  
15 level of activity for each of the positive peptides in a  
bar graph where the abscissa lists the HCV peptide  
(identified by a number that is uncoded in the following  
table) and the ordinate is demarked as percentage  
specific cytotoxicity.

The result of these assays was that significant  
20 cytotoxicity was observed in response to 7 out of 53  
peptides tested, as shown in Figure 1 and summarized in  
the following table. The peptide specific cytotoxicity  
after two weeks of culture at an effector to target cell  
ratio of 40 to 80/1 is shown. Cultures of subject C-3  
25 (Peptide 3) and H-1 (Peptide 5) were tested after three  
weeks of culture. HLA-A2 matched JY EBV-BCL were used in  
all cases as target cells.

Summary of HCV-Peptide Specific CTL Responses

	<u>HCV</u>	<u>aa Residues</u>	<u>HCV-Peptide (in Figure 1)</u>	<u>Subjects Responding</u>
5	Core	131-140	1	C-2,C-5
	Core	178-187	2	C-2,C-3
10	NS3	1169-1177	3	C-3
	NS3	1406-1415	4	C-2,C-3,C-5
	NS4	1789-1797	5	C-2,H-1
15	NS4	1807-1816	6	C-3
	NS5	2252-2260	7	C-2

20

In summary, then, four of the eight subjects showed CTL responses to at least one of the 53 peptides. Subject C-2 responded to five peptides, two of which are derived from HCV Core, and one from each of NS3, NS4 and NS5. Subject C-3 responded to four peptides, including HCV Core<sub>178-187</sub> but not HCV Core<sub>131-140</sub>. C-5 in contrast recognized HCV Core<sub>131-140</sub> and not HCV Core<sub>178-187</sub>. Subject H-1 responded to only one peptide: NS4<sub>1789-1797</sub>. Several of the peptides were found to be stimulatory for more than one patient, probably reflecting a higher degree of immunogenicity. Four of the subjects (C-1, C-4, C-6, H-2) did not show any significant induction of CTL activity with this panel of peptides or the remaining 46 peptides in the panel employed in this study. CTL responses were detected in 3 of 6 patients with chronic active hepatitis and 1 of 2 subjects with normal liver enzymes.

30

35

40

Characterization of HCV peptide specific CTL lines and clones. Figure 2 displays data derived from an example of typical CTL lines specific for HCV peptides obtained from Subject C-3. The abscissa of Figure 2 is labeled "Effector/Target Cell Ratio," where "effector" refers to the HCV-peptide used; the ordinate is labeled

"% Specific Lysis." Data points indicated by solid circles (●) display specific lysis of peptide-pulsed HLA-A2 matched JY EBV-BCL cells and open circles (○) display specific lysis by unpulsed cultures of the same cells.

5 The CTL lines had been four weeks in culture prior to the CTL assay, and received weekly restimulations with peptides and autologous feeder cells. As shown, these cell lines are specific for HCV Core<sub>178-187</sub> (panel 2A), NS3<sub>1169-1177</sub> (panel 2B), and NS3<sub>1406-1415</sub> (panel 2C) and recognize and  
10 lyse HLA A2-matched EBV-BCL in a dose dependent fashion.

In order to establish highly cytotoxic T cell lines for further study and generation of CTL clones, a restimulation protocol involving weekly restimulation with autologous irradiated PBMC, peptide and IL-2 was  
15 used. For most of the lines identified, a 2-4 fold increase of cytolytic activity on a per cell basis of each week was observed. For the CTL response of subject C-2 to NS5<sub>2252-2260</sub>, a significant cytotoxic activity after 2 weeks of stimulation of 29% at an E/T ratio of 40/1 was  
20 observed. A similar culture using PBMC collected two months later resulted in no significant CTL activity detected after 2 and 3 weeks of stimulation. Continuing restimulation with autologous PBMC and peptide revealed peptide specific CTL after 4 and 5 weeks, however. This  
25 may reflect fluctuation of the CTL precursor frequency in the course of HCV infection.

HLA Restriction analysis. An example of an HLA class I restriction analysis is shown in Figure 3. This analysis is done with a cytotoxicity assay as described  
30 in Example 2, using EBV-BCL cells that were peptide pulsed (closed circles; ●) or not peptide pulsed (open circles; ○) and target cells that display different HLA class I alleles, namely HLA-A2/Cw7 (panel 3A), Cw7 (panel 3B), A2 (panel 3C), and A3 (panel 3D). As shown, the  
35 presence of the HLA-A2 allele alone is both required and sufficient for recognition and lysis of target cells by

the CTL line specific for HCV core<sub>178-187</sub> derived from subject C-3, who is HLA-A2, A3, B44, Cw7. In view of the CTL induction protocol, rigorous HLA-restriction analysis such as this was not performed because the EBV-BCL target cell most frequently used in our study (JY) is HLA-A2, B7 and Cw7 positive. It is theoretically possible that effectors to NS4<sub>1789-1797</sub> and NS5<sub>2252-2260</sub> from subject C-2 recognize epitopes in the context of B7 and Cw7 and those derived from subject H-1 and specific for NS5<sub>2252-2260</sub> recognize epitopes in the context of Cw7. Effectors from subject C-5 share only the HLA-A2 allele with the target cells.

Cell surface phenotype. Cytotoxic T cell clones were derived from lines by cloning, using limiting dilution as described in Example 2. The resulting six clones were isolated from three donors recognizing epitope Core<sub>131-140</sub> and NS3<sub>1406-1415</sub>, which clones were used for a test of peptide specific cytotoxic activity at different numbers of effectors per target cell (E/T), which was the JY cell line. The test for cytotoxic activity used was the 4 hour <sup>51</sup>Cr-release assay described in Example 2, the results of which are shown in the table below. The clones from subject C-2 and C-5 were analyzed by flow cytometry and all were found to be CD8<sup>+</sup>, i.e., all of the clones were restricted to HLA class I.

HCV Specific CTL Clones

	Subject	Peptide	Clone	Cytotoxicity		FACS	
				E/T	%	CD4 <sup>+</sup>	CD8 <sup>+</sup>
5	C-2	Core <sub>131-140</sub>	R-14-115	3 1 0.3	67 42 27	1.4	83.6
10	C-5	Core <sub>131-140</sub>	H15-17	128 43 14	90 97 94	2.4	84.3
15	C-5	Core <sub>131-140</sub>	H15-26	68 22 7	84 89 76	1.9	97
20	C-5	Core <sub>131-140</sub>	H15-99	92 30 10	90 79 50	1.7	98
	C-3	NS3 <sub>1406-1415</sub>	D55-3	0.9 0.3 0.1	44 16 5	nd	nd
25	C-3	NS3 <sub>1406-1415</sub>	D55-10	18 6 2	69 66 58	nd	nd

30        Recognition of endogenous antigen. Recognition and  
 lysis of target cells that synthesize viral antigen  
 endogenously was demonstrated, the results of which are  
 portrayed in Figure 4. Figure 4 is divided into two  
 35 panels, namely panel 4A directed to the analysis of a CTL  
 line from subject C-5 and panel 4B directed to the  
 analysis of the D55-3 clone derived from subject C-3,  
 both of which are specific for NS3<sub>1406-1415</sub>. The abscissa is  
 labeled "Effector/Target Cell Ratio" and the ordinate is  
 40 labeled "% Specific Lysis." Target cells were HLA-A2  
 matched EBV-BCL that had been pulsed with NS3<sub>1406-1415</sub> peptide  
 (closed circles; ●) or medium alone (open circles; ○); or  
 that had been infected with a recombinant vaccinia virus  
 construct containing the HCV amino acid sequence 364-1619  
 45 (closed squares; ■) or with the same vaccinia virus  
 without the HCV sequence (open squares; □).

As can be seen in Figure 4, the CTL line as well as the clone recognize both endogenously synthesized antigen presented by recombinant vaccinia virus infected EBV-BCL as well as exogenously added peptide. Therefore CTL expanded in vitro with peptide retain the ability to recognize and lyse naturally-occurring virus infected target cells.

#### Example 4

This example illustrates a comparison of the sequences of peptides of the present invention to sequences contained in HCV belonging to different isolates.

Using sequences of HCV types deposited in GenEMBL as of January, 1993, a comparative analysis was conducted between the HCV-specific CTL epitopes as represented by the peptides of the present invention and GenEMBL sequences of different isolates of the different HCV subtypes currently identified. See Okamoto et al., J. Gen. Virol., 73, 673-679 (1992). The data is presented below in tabular form, wherein the subtypes are numbered I to IV, ND refers to those HCV isolates where the subtype was not determined, and the results of the comparisons between the listed peptides of the present invention and the corresponding regions of the various HCV subtype genomes is presented as x/y where x is the number of sequences that show no amino acid substitutions within a given epitope and y is the total number of sequences deposited in GenEMBL covering a given epitope.

	HCV	aa Residues	HCV Subtype				
			<u>I</u>	<u>II</u>	<u>III</u>	<u>IV</u>	<u>ND</u>
5	Core	131-140	3/3	8/8	1/3	2/2	7/8
	Core	178-187	3/3	1/11	0/3	2/2	2/8
10	NS3	1169-1177	2/3	0/5	0/1	0/1	0/1
	NS3	1406-1415	4/5	0/5	0/1	0/1	0/1
	NS4	1789-1797	3/3	0/5	0/1	0/1	0/1
15	NS4	1807-1816	3/3	5/5	0/1	0/1	1/1
	NS5	2252-2260	3/3	0/5	0/1	0/1	0/1

20        Accordingly, HCV displays considerable sequence  
 variability, as demonstrated by the above data regarding  
 the known HCV subtypes. It is important for the design  
 of both therapeutic and prophylactic applications of the  
 present invention that peptides be identified that are  
 25        present in the greatest number of different subtypes  
 predominant in a region of interest. As noted above, the  
 peptide sequence NS3<sub>1406-1415</sub> (SEQ ID NO:28) was recognized by  
 CTL from three subjects and is present in four out of  
 five HCV I subtypes predominant in the United States and  
 30        Europe. The fifth isolate, HCV-H, differs only with  
 respect to one conservative Ileu to Val substitution in  
 position 7.

#### Example 5

35        This example illustrates the ability of a patient's  
 CTL cells to be restimulated by autologous antigen  
 presenting cells.

Using the methods recited in Example 2, PBMC were  
 stimulated with the HCV-derived synthetic peptides of the  
 40        present invention and restimulated weekly with autologous  
 antigen presenting cells and peptide. Cultures were  
 tested initially after two weeks, then at weekly  
 intervals for peptide specific CTL activity against

target cells, as described. In the table below, peptide specific cytotoxic activity ( is presented for different numbers of effectors per target cell (E/T) obtained in a 4 hour <sup>51</sup>Cr -release assay for PBMC cells after 2, 3, 4, and 5 weeks of incubation.

For the data concerning subject C-2 and the NS5 peptide, the PBMC for experiment I were collected two months before experiment II. The patient had not received any treatment during this period.

10

	Subject	Peptide	2 weeks		3 weeks		4 weeks		5 weeks	
			E/T	%	E/T	%	E/T	%	E/T	%
15	C-2	Core <sub>131-140</sub>	80	61	25	50	72 24 8	76 71 43	30 10 3	76 78 51
20	C-2	Core <sub>178-187</sub>	80	29	25	37	64 21 7	81 64 33	18 6 2	60 57 24
25	C-3	Core <sub>178-187</sub>	80	19	40	18	33 11 4	60 37 20	30 10 3	76 52 35
30	C-2	NS5 <sub>2252-2260</sub> Exp I	40	29	nd					
30		NS5 <sub>2252-2260</sub> Exp II	40	2	25	3	88 29 10	59 29 10	56 19 6	83 52 20
35	C-2	NS3 <sub>1406-1415</sub>	80	24	25	11	56 19 6	60 30 14	22 7 2	29 14 7

Accordingly, specific cytotoxic activity of circulating cells and their ability to be restimulated were shown, both of which are requisite attributes of a CTL-based vaccine.

#### Example 6

This example illustrates a method for provoking an immune response to molecules containing HCV-derived peptides and/or peptides substantially homologous thereto in a mammal.

5     Med., 171, 1815-1820 (1990) or Kast et al., Proc. Natl.  
Acad. Sci USA, 88, 2283-2287 (1991), or using spleen  
cells, by the method of Harty et al., J. Exp. Med., 175,  
1531-1538 (1992). Protection against HCV infections can  
be achieved by CTL induced by either of these  
10 immunization procedures.

15           While this invention has been described with an  
emphasis upon preferred embodiments, it will be obvious  
to those of ordinary skill in the art that variations of  
the preferred embodiments may be used and that it is  
intended that the invention may be practiced otherwise  
20   than as specifically described herein. Accordingly, this  
invention includes all modifications encompassed within  
the spirit and scope of the invention as defined by the  
following claims.
